## Abstract

Environmental matrices are polluted with the plethora of contaminants, and among these, the concerns related to heavy metals (HMs) are also included. Due to the low cost in a long-term application and environmental friendliness, the use of biological remediation has gained significant attention in recent decades. The use of ornamental plants (OPs) in the field of phytoremediation is scarcely reported, and the impacts of HMs on OPs has also not been investigated in great depth. The OPs mediated HMs remediation can simultaneously remove contaminants and bring improvement in aesthetics of the site. The biomass of OPs produced after such activities can be used and sold as pot plants, cut flowers, essential oils, perfumes, air fresheners production, metal phytomining, and feedstock in silk production. The OPs also present a lower risk of HMs bioaccumulation compared to crop plants. This review focuses on the current knowledge of HMs toxicity to OPs, their applicability advantages, methods to improve the tolerance of OPs with incremented HMs uptake, challenges in the field, and future application perspectives. The practical application of OPs case studies from China, Iran, India, Oman, Pakistan, and Turkey was also discussed. This work fetches the inter-disciplinary features and understanding for the sustainable treatment of HMs in a new novel way, to which no previous review has focused.

**Keywords:** Ornamental plants, heavy metals, horticulture, phytoremediation, plant toxicity

## 1. Introduction

The expanding human population needs a substantial amount of product and services to maintain the livelihood on earth (Shang et al., 2019). The human population is going through an exponential phase, hence adopting a j-shape graphical growth, that is not converted into s-shaped and sustainable development, catastrophic environmental events are expected (Cazalis et al., 2018). The menace related to environmental pollution is already evident, due to the unsustainable human development, greedy economic growth, and compromise on ecological sustainability (Vita et al., 2019). In the recent decade, some well-known hazards that came into debate were linked to heavy metals problems.

Technically, the term “heavy metals” does not have a compressive definition, defining it in terms of toxicological, physical, biological and chemical aspects (Pourret, 2018). But due to its broad use and unavailability of another word to replace it, the name heavy metals “HMs” should not be considered an offence to science. Heavy metals are of concern due to their capacity to induce harmful and toxic effects on plants and animals. Some HMs are known to have importance in growth at minute quantities (Cu, Fe, Mn, Zn, and Mo), but surplus levels negatively affect growth and development (Alirzayeva et al., 2017). Another major problem associated with them is the capacity to bio-magnify in the food chain (Arshad et al., 2017; Majed et al., 2016). They are the part of earth composition, present in different ores.

Further, they are indestructible. The xenobiotic concentration of HMs leads to an environmental problem because of their toxic, non-biodegradable and persistent nature (El-Naggar et al., 2018). In such a condition, choosing plants that can take up HMs with reduced risk of biomagnification is significant merit. For these ornamental plants (OPs) are the potential candidates. These include aquatic and terrestrial herbs, shrubs, or trees cultivated for soft landscaping and decorative purposes. Standard ornate features include leaves, scent, fruit, stem, and bark.

In this literature review, impacts of heavy metals on plant growth, notably ornamental plants, possible use of OPs in phytoremediation of HMs, and application in green and blue-green infrastructures are discussed. The HMs response of OPs was reviewed against, but not limited to, Cd, Cr, Cu, Ni, and Pb. Due to the frequent uses and release of these HMs in most domestic and industrial activities and notorious environmental impacts this review's discussion is centred more towards these HMs (Iqbal et al., 2019; Khan et al. 2019a). Methods through which the

1 tolerance of ornamental plants can be enhanced, with the pros and cons are also discussed. This  
2 review also iterates the knowledge related to the use of ornamental plants in research as the  
3 model plant in the field of phytoremediation. Critical due attention was shaded on the  
4 dendroremediation of HMs using ornamental trees. The current challenges associated with  
5 ornamental plants' usage in green and blue-green infrastructures and phytoremediation of HMs  
6 are discussed. The importance of continual screening of novel plants, particularly the  
7 previously neglected ornamental plants, has also been highlighted.

8  
9 Further, the review also presents understanding for step required for establishing an operational  
10 constructed wetland using OPs and OTs. This review can contribute towards the identification  
11 of new and more effective phytoremediation approaches. Hence, this review's main objectives  
12 included established the understanding that OPs can play a role in HMs phytoremediation.  
13 Through this review, it was emphasized that though there is room for opportunity, care should  
14 be taken to select and screen OPs. It helps identify potential OPs, and can also reduce an  
15 economic loss if a wrong non-tolerant OPs is selective for urban green spaces.

## 27 **2. Ornamental plants and trees under the influence of heavy metals**

### 28 **2.1. Response regarding HM uptake and compartmentalization**

29  
30 The exposure to these selected metals (including Cu, Cr, Cu, Ni, and Pb) and OPs and other  
31 plants' physiological response are listed in Table 1. Notably, the reaction in some OPs is very  
32 drastic, while for other shows tolerance. The details related to the response of OPs upon metal  
33 uptake is as identical to that of other terrestrial and aquatic plants. A summary is presented in  
34 the supplementary information discussing the translocation and impacts selected metals within  
35 the plants. To counter these negative impacts, ornamental plants, like any other terrestrial or  
36 aquatic plants, utilize complex enzymatic and non-enzymatic machinery. Under normal  
37 conditions, OPs also produce a limited amount of reactive oxygen species (ROS) reported in  
38 chloroplasts, mitochondria, and peroxisomes (Murik et al., 2019).

39  
40 Generally, plants, including ornamental plants, are classified based on the metal uptake  
41 mechanisms. Excluders restrict HMs uptake and translocation to the shoot.  
42 Indicators/accumulators dynamically accumulate HMs in their above soil-plant parts  
43 comparatively the same as the soil levels. While hyperaccumulators uptake and translocate  
44 HMs to shoots and leaves without any toxic symptoms. Few examples of hyperaccumulator,  
45 accumulator and excluder, ornamental plants are presented in Table 2. In OPs, HMs

1 detoxification is primarily achieved through compartmentalization, deposition, distribution,  
2 and stabilization within the cell walls, vacuoles, and metabolically inactive tissues (Lajayer et  
3 al., 2019; Levizou et al., 2016). *Abelmoschus manihot* L. plants were reported to tolerate Cd  
4 toxicity through accumulation in vacuoles and cell wall (Wu et al., 2018).  
5  
6

7  
8 Similarly, Caldelas et al., (2012) reported Cr's compartmentalization by *Iris pseudacorus* L.  
9 (Common name: Yellow iris) in the root cortex cell wall and the intercellular spaces of rhizome  
10 cytoplasm. Chelation of the HMs by a ligand, followed by the sequestration of the metal-ligand  
11 complex into the vacuole is another potential mechanism of HMs tolerance in OPs.  
12 Biochelators are needed for the HMs detoxification by the plant cell (Liu et al., 2017). These  
13 include metallothioneins (MTs), organic acids, and phytochelatins (PCs). As bio-chelator  
14 synthesis is an energy-consuming process that can limit the plant growth, it is not used very  
15 frequently by metallophytes. Metallophytes perform HMs compartmentalization through  
16 translocation. While in non-metallophytes, these bio-chelators contribute to stress due to shift  
17 metabolic towards defence (Lajayer et al., 2019).

## 27 **2.2. Notable OPs families studied for HMs remediation from environmental matrices**

28  
29 Ornamental plant many plant families has been subjected to phytoremediation studies.  
30 Members of Lamiaceae family, mostly include annual herb and shrubs, were tested for HMs  
31 tolerance. Among them included *Anethum Graveolens* (Common name: Indian Dill),  
32 *Lavandula vera* and *Lavandula anqustifolia* (Common name: English lavender) that were used  
33 for soil HMs remediation, and the biomass produced is reported to be used for essential oil  
34 production (Angelova et al., 2015; Barouchas et al., 2018; Zheljazkov et al., 2006).  
35  
36

37 From Solanaceae family, the *Petunia* (Perennial and annuals herbaceous plants) and *Nicotiana*  
38 (Tall, bushy tender perennial plants) genera have been used extensively used in research as  
39 model plants (Khan et al., 2019ab; Taheri-Dehkordi et al., 2018). Both plants Very commonly  
40 used plants, and many have economic value in the horticulture market. Notable *Petunia* species  
41 included *P. axillaris*, *P. exserta*, *P. grandiflora*, *P. hybrida*, *P. inflata*, and *P. integrifolia* (Khan  
42 et al., 2019b; Silva et al., 2018). For *Nicotiana*, *N. alata*, *N. benthamiana*, *N. clevelandii*, *N.*  
43 *glauca*, *N. plumbaginifolia*, *N. rustica*, *N. sylvestris*, and *N. tabacum*, have been used in  
44 multiple studies (Chen et al., 2015; Vallejo et al., 2015; Wu et al., 2011). The plants from both  
45 genera have also been used in many phytoremediation experiments, including treating dyes,  
46 heavy metals, and organic contaminants. However, research related to intrinsic plant potential,  
47 the effect of soil amendments, and plant-microbe interactions concerning heavy metals

64  
65

1 exposure are minimal for *Petunia hybrida* L. and *Nicotiana glauca* L., despite their well-  
2 developed market.

3 Plants belonging to Asteraceae family, like *Tagetes erecta*, *Calendula officinalis*, and  
4 *Chrysanthemum indicum*, were also reported to perform well in HMs contaminated soils  
5 (Coelho et al., 2017; Goswami and Das, 2016; Mani et al., 2015). All these plants are known  
6 to have economic values in floriculture and horticulture. Hence, it can be forecasted that HMs  
7 phytoremediation through OPs brings dual benefits. These include the HMs removal and along  
8 with the simultaneous beautification of the site. Some of the OPs used in HMs  
9 phytoremediation were presented in Table 1, 2, and 3.

### 16 **2.3. Dendroremediation of HMs using ornamental trees**

17 Phytoremediation, using small herbaceous OPs, can only be applied for shallow depth, where  
18 plants' roots can penetrate and interact with metals. The use of trees for the clean-up of  
19 contaminants is known as dendroremediation. This word is originated from the Ancient Greek  
20 *dendron* meaning “tree” and Latin *remediare* representing “reuse”. The HMs remediation at  
21 higher soil depths with ornamental trees and shrubs offer a selective advantage over OPs. These  
22 include the deep rooting system (Saxena et al., 2019). Many contaminants can be targeted using  
23 ornamental trees and shrubs (OTs) mediated dendroremediation (Komives and Gullner, 2006).  
24 These systems perform hydraulic retention of HMs, preventing HMs from entering the  
25 saturated aquifers (Hashim et al., 2011). They also act as a riparian buffer to avoid the nutrient  
26 and HMs from city and agricultural runoff getting into freshwater streams (Komives and  
27 Gullner, 2006). Further, these systems also can potentially remediate brownfields (pieces of  
28 land that was previously developed land used for industrial activities but not currently in use  
29 due to potential contamination) (Saxena et al., 2019).

30 *Populus deltoides* Bartr. ex Marsh. clone ‘Bora’ (Common name: Eastern cottonwood) and  
31 *Salix viminalis* L. clone ‘SV068’, (Common name: Basket willow) were reported to  
32 phytoextract Zn and Cd in aerial parts, while Cr, Ni, Pb, and Cu were phytostabilized in the  
33 roots (Pilipović et al., 2019). Jiang et al., (2019) reported that 1.92–7.89 g Cd and 9.70–83.58 g  
34 Pb every year can be phytoextracted by a hectare *Morus alba* (Common name: Mulberry tree)  
35 shoot. They also concluded that these trees could be an alternative plant to use heavy metal  
36 polluted paddy soils. The similarity in another study conducted by Wan et al., (2017), reported  
37 that *M. alba* planting is safe on soils with Pb and As concentrations lower than 369 and 180 mg  
38 kg<sup>-1</sup>, respectively. Further, Silkworms fed with mulberry leaves collected from slightly  
39

1 contaminated soil exhibited productive growth and normal silk production. As bioindicators,  
2 trees can be used to study the historical concentrations of atmospheric HMs. Turkyilmaz et al.,  
3 (2019) studied the deposition of Al, As, B, Ba, Ca, Cd, Cr, Cu, Fe, Mg, Mn, Na, P, and Zn in  
4 the rings of *Quercus laevis* (Common name: Oak trees). They concluded a significant positive  
5 relationship between the HM concentrations in tree rings and the concentrations of atmospheric  
6 HMs, at a confidence interval of 95% for As, 99% for Cd, and 99.9% for other elements.  
7  
8  
9

10  
11 The OTs can utilize the leftover contaminated urban land gets contaminated, and but the use of  
12 natural vegetation they can accumulate HMs. Abbas et al., (2019) conducted one such study.  
13 They reported using *Prosopis glandulosa* (Common name: Honey mesquite tree) to perform  
14 phytoremediation of sewage sludges and sewage-amended soils. The contaminated soil was  
15 polluted with metals such as Cd, Zn, Ni, Co, and As. They concluded that *P. glandulosa*  
16 concentrated more Cd, Cu, Fe, Pb, and Zn in its aerial part, As, Co, and Ni was evenly  
17 distributed in the tree. Like any other trees, the OTs are sustainable solar energy-driven pumps,  
18 and they can control significant phytohydraulics that has the potential for hydraulic retention  
19 through evapotranspiration. It is an excellent approach to control subsurface percolation of the  
20 HMs with water. One such study was conducted by Nguyen et al., (2020), who, by the help of  
21 the simulation model, presented mangroves' potential in the retention of chromium. This case  
22 study was conducted in the Thi Vai River Catchment, Vietnam. Like the OPs, OTs are also  
23 used in the field.  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34

35 The distant advantage of their usage is that the biomass produced can be used for timber, scent  
36 wood, or pulp and paper production. A few examples of such OTs included *Azadirachta indica*  
37 (Common name: Neem tree) belonging to Meliaceae family, *Holoptelia integrifolia* (Common  
38 name: English beechwood) belonging to Ulmaceae family, *Gmelina arborea* (Common name:  
39 belonging to Verbenaceae family, *Dendrocalamus Strictus* (Common name: Bamboo)  
40 belonging to Poaceae, and *Leucaena leucocephala* (Common name: River tamarind) belonging  
41 to Fabaceae family (Pandey and Souza-Alonso, 2019). These findings will support the  
42 practicability of these plants for the phytoremediation of heavy metals. Understanding the  
43 tolerance potential of these plants can also reduce capital loss and atheism when exposed to  
44 HMs. All these trees are known to produce vegetative canopies and can be grown in urban  
45 areas. Hence, they can be used for the recreational purposes of the contaminated brownfields.  
46 The list of such OPs and OTs having the capacity to perform HMs phytoremediation is  
47 improving over time. However, more research in term of practical application is needed.  
48 Further, the season-dependent effectiveness, slow growth, lack of suitable monitoring methods,  
49

65

1 and unique constraints require action for successful application in the future (Redfern and  
2 Gunsch, 2016).

### 3. Advantages for OPs mediated HMs remediation and current knowledge related to 4 their applications in green and blue-green infrastructure 5 6 7

8 Due to the capital-related, technical, and environmental problems, conventional physical and  
9 chemical remediation (including chemical precipitation, adsorption, ion exchange, membrane  
10 filtration, coagulation-flocculation, floatation, physical encapsulation, soil excavation) are less  
11 feasible for the field application (Mahmood 2010; Lajayer et al., 2017). The use of plants for  
12 the remediation has gained considerable attention for absorption, accumulation, and transfer of  
13 contaminants from the environment within plants, which can occur within edible and non-  
14 edible parts. Further, some studies reported using grasses, OPs, and trees (Lajayer et al., 2019;  
15 Maleki et al., 2017). The use of crop plants should not be promoted for the phytoremediation.  
16 It is due to the possibility of HMs biomagnification in the food chain (Cazalis et al., 2018; Gill  
17 and Tuteja, 2011). As it is a threatening issue for human and animal health, the use of  
18 ornamental plant species is a more workable option. With tremendous diversity and abundance  
19 of many available OPs, it will be beneficial to screen the potential local OPs for the  
20 phytoremediation of HMs contaminated environments (Lajayer et al., 2019). One distinct  
21 advantage of the use of OPs is the simultaneous improvement of the aesthetics and the cleaning  
22 of the contaminated site, which can be even more acceptable for the urban areas and green  
23 infrastructures (Haase, 2015; Prapagdee and Wankumpha, 2017). Depending on the  
24 contaminated environmental matrices (soil, water, or air), the OPs are categorized into aquatic  
25 and terrestrial plants (Nakbanpote et al., 2016). Few examples OPs used for the exposure  
26 analysis and phytoremediation of HMs-contaminated matrices were presented in Table 2 and  
27 Table 3.  
28

44

45 A very massive portion of the world's population (more than 50%) is living in cities due to the  
46 rapid migration towards the urban cities, and future population growth is further expected to  
47 happen in urban centres (Haase, 2015). The most common reasons expected to induce problems  
48 associated with the HMs exposure are contributed by industrial, domestic, economic, and  
49 transportation sectors (Arbolino et al., 2018), whereas, the contribution of enhancement in the  
50 living standards cannot be neglected. The leading cause of this will be the compromise on  
51 sustainability leading to contamination of environmental matrices (Vita et al., 2019). In past  
52 decades, to overcome HMs contamination problems, attention has been given to green and blue-  
53  
54

65

1 green infrastructures. A green infrastructure (GI) is a deliberately cultivated system of natural  
2 and semi-natural zones and other environmental features that are constructed and accomplished  
3 to offer a wide range of ecosystem services' in rural and urban areas (Calvert et al., 2018). A  
4 blue-green infrastructure (BGI) is an extension to the concept of GI. The BGI also includes  
5 good water management restoring, or mimicking the natural water cycle, and is anticipated to  
6 be embraced at the industrial and local scale for the efficient closed-loop circulation of  
7 freshwater (Martinico-Perez et al., 2018). Both GI and BGI are essential for the sustainability,  
8 liability and healthfulness of any setting, whether natural or anthropogenic, as they provide  
9 numerous welfares and aid to the human and associated environment. These include sustainable  
10 tackling of the impact related to climate change, improving the aesthetic quality of the built  
11 environment air, water, and wastewater quality, protection and enhancement of the  
12 biodiversity, and offering places for relaxation, physical activity, and play (Calvert et al., 2018;  
13 Martinico-Perez et al., 2018). These sustainable infrastructures can also contribute to air  
14 remediation through OPs canopy, capturing the particulate matter with deposited HMs using  
15 leaves, fruits, wood, and flowers surfaces (Schreck et al., 2012). Further, these OPs canopies  
16 growing in urban areas act as competent collectors of re-suspended dust and can also be used  
17 as air bio-monitors and bio-indicators (Lajayer et al., 2019).

31 The special OPs for HMs (Cd, Pb, Zn, and Ni) with accumulation potential are *Acer negundo*  
32 L. (Common name: Boxelder maple), *Ailanthus altissima* (Mill.) Swingle (Common name:  
33 Tree of heaven), *Fraxinus angustifolia* Vah l. (Common name: Desert ash), and *Robinia*  
34 *pseudoacacia* L. (Common name; Black locust) and hence the canopy of such plants can reduce  
35 the HMs exposure to other living organisms. Use of GI and BGI, like constructed wetlands,  
36 have been well reported to remediate HMs in soil, water, and wastewater (del Carmen Durán-  
37 Domínguez-de et al., 2018; Sandoval et al., 2019). It is not only achieved by the plant uptake  
38 or stabilization, but also by the plant litter. Plant litter acts as a bio-sorbent and includes debris,  
39 cellulose, cutin, fibres, lignin, pectin, suberin, and wax, that perform sorption of metal ions  
40 (Vithanage et al., 2012).

51 A better understanding of GI/BGI and HMs tolerant OPs can also benefit the grey  
52 infrastructures, which are the conventionally used wastewater treatment facilities, at industrial  
53 and domestic scale (Qi et al., 2019). These grey infrastructures contribute to the current 60%  
54 of urban surfaces, primarily pavements and roofs. The usage of OPs, in both GI and BGI, will  
55 be encouraged in future, with the enhancement in living standards and cities. Unfortunately,  
56  
57  
58  
59

1 minimal attention has been given to this possibility. The existing limited freshwater and clean  
2 soil resources are already stressed due to climatic changes and an increase in the human  
3 population (Ha et al., 2018). The chances are high that for sustaining the growth and  
4 maintenance of GI and BGI, irrigation with treated wastewater or greywater would be needed.  
5 The exposure to contaminated dust due to automobile and pedestrian can affect the performance  
6 of OPs in GI and BGI (Wang and Zhou, 2005). Previously reported HMs tolerant OPs (Table  
7 2) and the new OPs would be the key players in such infrastructures.

13 Industries are among the potent site that is known to cause significant anthropogenic pollution  
14 of limited freshwater bodies. According to sustainable development goal (SDG) 6.6, protection  
15 and restoration of water ecosystems is a must by 2020. In the scenario of developing countries,  
16 the physicochemical method is not feasible; due to applicability limitation, the problem  
17 associated with rejects dispersal and high capital cost (Aziz et al., 2008). Utilization and  
18 optimization of alternate technologies are essential to achieve SDG 6.4, i.e. reducing,  
19 eliminating, and minimizing the improper disposal. Hence finding an appropriate combination  
20 of plants, that can withstand the harsh conditions, is one of the challenges needed to be  
21 addressed earlier, for the successful delivery, management, and planning in an uneven picture  
22 of GI and BGI. Therefore, green infrastructure benefits must be maximized whilst being  
23 mindful of the cost of delivery and maintenance. For industrial wastewater, where the  
24 concentration of HMs, level of salinity, fluctuation of pH, and amounts of dissolved solids are  
25 relatively high, it is impossible to use OPs directly in GI and BGI for treatment of wastewater.  
26 Similarly, the domestic wastewater also needs to be characterized, as the most prominent issues  
27 with domestic wastewater usage are the higher biological oxygen demand, chemical oxygen  
28 demand, total suspended solids, and total dissolved solids. It is first essential to characterize the  
29 wastewater; if needed, the wastewater can be pre-treated using physicochemical methods. It  
30 can even be diluted, before irrigation of OPs and OTs. No matter which design model is used  
31 for municipal sewage, the area of horizontal flow constructed wetlands is usually about 5 m<sup>2</sup>  
32 Population Equivalent<sup>-1</sup>. It is recommended that the respective inflow loads of 6 g m<sup>-2</sup> day<sup>-1</sup>  
33 and 20 g m<sup>-2</sup> day<sup>-1</sup> should be maintained to achieve the outflow BOD<sub>5</sub> and TSS concentration  
34 of 30 mg L<sup>-1</sup> (Vymazal, 2010). Further, the OPs and OTs can also be used in GI and BGI for  
35 nutrient removal in the final stages of the wastewater treatment system, as the polishing step  
36 (Marín-Muñiz et al., 2020).

1 The OPs, after HMs phytoremediation, can be used for utilitarian purposes from the harvested  
2 vegetation and flower (Nakbanpote et al., 2016). The biomass produced can be used for  
3 valuable products like pot plants and cut flowers. Further, flower cuttings can be sold in flowers  
4 shop, while their essential oils and fragrant wood can be used for perfume and air freshener  
5 production. There is no previous report on HMs exposure through the perfumes obtained from  
6 OPs cultivated on HMs contaminated matrices. Based on the absence of HMs in essential oils  
7 of medicinal and aromatic plants, it can be hypothesized that the perfumes produced from parts  
8 of OPs using the distillation methods are free from HMs and can be safely promoted with no  
9 risk to human health (Lajayer et al., 2017; Raza et al., 2019). Although there is no documented  
10 evidence for the presence of HMs in essential oils obtained from OPs, there is still the need to  
11 prove this with the help of concrete scientific evidence after thorough experimentation on OPs-  
12 HMs system. Optimistically, OPs can generate considerable revenue by selling cut flowers,  
13 produced after exposure and cultivation on HMs containing matrices by utilizing the  
14 brownfields. The application of OPs in the field can be distributed into four phases, with key  
15 checkpoints at each step.

### 26 **3.1. Phase 1: Initial site assessment**

27  
28  
29  
30  
31 During this phase, necessary information related to site and matrices to be treated. The  
32 parameters included for monitoring included the contained site's total related chemistry, as it  
33 varies from one place to another. It must be performed to effectively account and quantify the  
34 different constituents that can interfere with one another and plants. The quantification of  
35 chemical composition will help select prospective OPs and OTs. Further, it can also assist the  
36 expected changes in the composition of soils rhizosphere microbes. The plant parameters that  
37 can be checked include plant biomass, height, and covered vegetative area. The most practical  
38 biochemical status of OPs and OTs, while in the field include the plant pigments (chlorophyll  
39 contents). To evaluate the aesthetic quality index of visual quality can be created. A model  
40 quality index ranged from 1 to 5, indicating non-commercial to outstanding quality. Based on  
41 leaf discolouration, leaf necrosis, defoliation, and flowering are presented in supplementary  
42 table 1.

### 43 **3.2. Phase 2: Off-site testing and pilot-scale optimization**

44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57 After identifying the site's elemental composition, soil status, and selection of potent OPs, the  
58 design of a constructed wetland system must be finalized. It can be performed in lab-controlled  
59  
60  
61  
62  
63  
64  
65

1 conditions. As the state is controlled the status of design system upset can be estimated. The  
2 parameters that can be noted include the changes in temperature, flow rate, water chemistry  
3 (including biological oxygen demand, total suspended solids, total dissolved solids, organics',  
4 and inorganics' composition). Through early testing, these parameters, a robust and predictable  
5 treatment is possible though construed wetland. This activity can be extrapolated toward field  
6 application and can help enhance the accuracy of initial size estimates for the full-scale  
7 treatment wetlands. The pilot-scale optimization checklist is presented in supplementary table  
8  
9  
10  
11  
12  
13 2.

### 14 15 **3.3. Phase 3: On-site execution and performance monitoring**

16  
17  
18 Through the findings of phases 1 and 2, an on-site prototype of the constructed wetland should  
19 be is designed at a small scale, to test the system workability. Through this, the final detailed  
20 optimization, according to the site, can be made. If needed, any changes in the design can be  
21 introduced before constructing the full-scale system.  
22  
23  
24

### 25 26 **3.4. Phase 4: Operational full-scale system**

27  
28  
29 At phase 4, with the trail of phase 1, 2, and 3, a well-designed, appropriately sized constructed  
30 wetland can be established to achieve the desired goals. For a full-scale operational system,  
31 there is the need to provide acclimatization time to plant and microbes to achieve wetland  
32 maturation. Throughout this phase, regular monitoring is needed. It is performed to assess the  
33 efficiency and reduce the risk of divergences from the optimal treatment design. As the design  
34 system upsets were considered earlier at prototype scales, a decision matrix should also be  
35 maintained for the adaptive constructed wetland management.

## 43 44 **4. Methods to improve the tolerance of ornamental plants**

45  
46 The alteration in soil structure using soil amendments affects the tolerance and  
47 phytoremediation competence for HMs in the OPs. Based on the previous finding, there have  
48 been many methods adopted to improve the tolerance potential of OPs against HMs, and similar  
49 techniques can be tested for the OPs (Table 3). The soil conditions, changes in plant-microbe  
50 interactions, transgene introduction into plants, synthetic chelator use, and associating  
51 phytoremediation with other treatment methods have been investigated extensively (Lajayer et  
52 al., 2019; Liu et al., 2017). The schematic representation of how these methods can contribute  
53

2 to the improvement in the tolerance of OPs is presented in Figure 1, further detailed discussion  
3 on each process is conferred individually, in the proceeding section.

#### 4 5 **4.1. Use of soil conditioners**

##### 6 7 **4.1.1. Biochar**

8  
9 Biochar is manufactured by thermal degradation under limited oxygen availability using  
10 organic feedstock, including plant material, manure, rumen, and sludge (Jegajeevagan et al.,  
11 2016). Due to biochar's physicochemical properties, like high pH and carbon content, large  
12 surface area, and functional groups, it's amendment in soil results in modified soil microbial  
13 population, soil fertility, carbon sequestration, and improved soil physical properties (Iqbal et  
14 al., 2019). The composition and remediation capacity of biochar depend on the feedstock,  
15 pyrolysis temperature, and post-production modifications (Sanchez-Monedero et al., 2018).  
16 The application of biochar on various plants can behave differentially (positively, negatively,  
17 or neutrally). Further, there are legislations (in Europe) that do not allow the land application  
18 (Fascella, 2015), resulting in most of the lab-scale studies (Zhang et al., 2016).

##### 28 29 **4.1.2. Compost**

30  
31 Compost is one of the commercially available soil conditioners produced using a variety of  
32 organic materials typically produced after long aerobic decomposition at thermophilic ranges.  
33 These materials include plant fibres and debris, sludge, animal corpses, slaughter remain, and  
34 material rich in organic matter (Ngo and Cavagnaro, 2018). Compost has been widely used as  
35 a soil additive for ornamental plants. Its application is reported to promote the growth of  
36 *Calendula officinalis* L. (Common name: Marigold), *Petunia hybrida* L. (Common name:  
37 Petunia), and *Nicotiana alata* L. (Common name: Jasmine tobacco) (Gerats et al., 2005; Khan  
38 et al., 2019ab). It promotes the soil aeration by reducing the soil compaction, moisture retention,  
39 nutrient release, and reducing the mobility of contaminants like hydrocarbon and heavy metals  
40 (García-Delgado et al., 2019; Hussain et al., 2018). It has been reported to show synergistic  
41 positive effects on plant and soil parameters (Egene et al., 2018; Gong et al., 2018).

##### 52 53 **4.1.3. Peat-moss**

54  
55 Peat moss is one of the major soil conditioners produced commercially (Ángeles-Argáiz et al.,  
56 2016). It is produced by incomplete anaerobic decomposition of plants (typically *Sphagnum*  
57 and *Carex*) at low temperature, nutrient and pH (Bourgeois et al., 2018; Preston et al., 2012).

64  
65

It shows a slow degradation rate in soil, higher water holding and cation exchange capacity, high porosity, and low bulk density (Kern et al., 2017). Due to the acidic properties in the soil, it increases the HMs soil mobility (Lee et al., 2015), which can help improve the metal uptake within OPs capable of phytoextraction. It's ever-growing demand and cost are linked with environmental problems (Méndez et al., 2017). The use of peat moss alone should not be promoted and should be blended with other soil conditioners, or alternative materials should be used.

#### 4.1.4. Biosolids, vermicompost and fertilizers

Coir dust, manufactured with mesocarp tissue or coconut husk, is very cheap biosolid (Etim et al., 2016). It has been found to improve the plant growth, and experiments have shown that it can adsorb the HMs like Ni, Cu, and Zn (Swarnalatha and Ayoob, 2016). Vermicompost produced with the help of worms (notably red wiggler and white worms) mediated composting process and promotes plant growth. Mani et al., (2015) reported that with vermicompost and sulphur combined application on Pb-polluted soil, improvement of photosynthetic pigments and higher Pb phytoextraction by *Chrysanthemum indicum* L. was achieved. Alteration in the soil parameters, by augmentation of nutrients, can also promote plant tolerance. The phosphate addition resulted in higher arsenic uptake up to 265% in *Pteris vittata* (Common name: Chinese brake) (Cao et al., 2003). *Carpobrotus rossii* (Common name: Karkalla), an Australian native Cd hyperaccumulator, when grown in the presence of chemical N fertilizers and manure, showed improved shoot biomass, while with manure application reduction in Cd availability in soil was reported (Liu et al., 2016). Another study reported that NPK fertilizer significantly increased the cadmium uptake in *Cosmos sulphureus* (Common name: Sulfur cosmos) and *Cosmos bipinnata* (Common name: Mexican aster), in comparison to the control (Zhou et al., 2018). However, biofertilizers are more beneficial and sustainable than synthetic and chemical fertilizers, as they offer more macro and micronutrients to plants (Liu et al., 2017).

#### 4.2. Use of synthetic chelators and organic compounds

Synthetic chelators can also be used to study the influence of HMs on OPs growth (Habiba et al., 2015). The synthetic chelators were reported to negatively impact plant growth and rhizospheric microbial populations (Kalyvas et al., 2018). The use of DTPA (Diethylene triamine penta-acetic acid), EDTA (Ethylene diamine tetra-acetic acid), EGTA (ethylene glycol tetra-acetic acid), and SDS (Sodium dodecyl sulphate) is widespread to influence HMs mobility

1 within plant or retention in soil. The co-application of synthetic chelators instantaneously  
2 amplifies environmental contamination (Sarwar et al., 2017).  
3

4 Cui et al. (2007) studied the impact of sodium EDTA, oxalic acid, tartaric acid and citric acid,  
5 on the growth of *Zinnia elegans* Jacq. (Common name: Youth-and-age). They identified that  
6 the development of *Z. elegans* was better when equimolar exogenous chelators were provided  
7 concerning the metal concentrations. Similarly, the use of EDTA enhanced the Cd uptake in  
8 four ornamental plants, *Althaea rosea* (Common name; Hollyhock), *Lonicera japonica*  
9 (Common name; Japanese honeysuckle), *Salvia virgate* (Common name; Southern meadow  
10 sage), and *Dahlia hybrida* (Common name; Dahlia) (Cay et al., 2016). Khan et al. (2019a)  
11 reported that EDTA with *P. hybrida* significantly increased the HMs uptake (Cd, Cr, Cu, Ni,  
12 and Pd), but the higher uptake reduced plant's aesthetics and growth. Similarly, to improve the  
13 performance of OPs in HMs stressed environment use of citric acid, salicylic acid, humic acid,  
14 and fulvic acids as a bio-stimulant has also been discussed in detail by Canellas et al. (2015)  
15 and Wei et al. (2018). The use of synthetic chelators needs to be investigated with the OPs to  
16 conclude how OPs will behave when exposed to synthetic chelator and HMs.

### 29 **4.3. Influence of microbial factors on soil nutrient cycling and plant HMs tolerance**

30

31 One of the potential soil quality indicators is the soil microbial population and their activities  
32 (Graham et al., 2021). Plants are highly dependent on the microbiological process that mediate  
33 the mineralization of organic matter and convert them to readily available nutrients (Khan et  
34 al., 2017b). The microbial population is responsible for producing organic acids like humic acid  
35 and fulvic acids through bio-decomposition of organic matter. The produced organic acids act  
36 as a bio-stimulants for the plant growth as proposed by Wei et al. (2018). Hence, in natural and  
37 engineered biological remediation systems, a diverse and health soil microbial population plays  
38 a determinant role in managing a stable reserve of carbon and nitrogen, maintained by rapid  
39 biological decomposition living and dead organic materials (He et al., 2010). A detailed review  
40 of this matter was published by Chen et al. (2003), where the importance of actinomycetes,  
41 bacteria and fungi in biological C and N fixation was discussed in detail. Apart from nutrients  
42 cycling the microorganism, notably bacteria and fungi, play an active role in biological  
43 remediation and improve the plant tolerance against metal exposure (Khan et al., 2016ab). The  
44 proceeding section discusses the role of bacteria and fungi and mediating the reduction of HMs  
45 stress to plants.

#### 4.3.1. Bacteria

Microorganisms can influence the mobility and bioavailability of HMs in the soil (Arshad et al., 2017). They utilize different methods, including accumulation, acidification, bio-sorption, chelation, complexation, methylation, and redox reactions (Lin et al., 2018; Liu et al., 2017). Arshad et al. (2017) reported that the combined use of biochar with bacterial consortia of *Bacillus cereus* and *Pseudomonas japonica*, resulted in a reduction of Cr(VI) to Cr(III). This reduced phytotoxicity of Cr in *Triticum aestivum* L. (Common name: Wheat). It can be inferred that bacterial augmentation can play a significant role in increasing or decreasing the HMs mobility within the ornamental plants. In another study with *Helianthus annuus* (Common name: Sunflower) the addition of bacterial strains *Ralstonia eutropha* and *Chrysiobacterium humi* lead to a significant reduction in the plant weight loss due to the zinc and cadmium exposure (67 and 64%, respectively) (Marques et al., 2013). Another study with *Orychophragmus violaceus* (Common name: Chinese violet cress) reported that the bio-augmentation rescued the bacterial diversity by 83%, which was reduced due to soil contamination with Cd and Zn (He et al., 2010). Properties like production of 1-aminocyclopropane-1-carboxylate (ACC) deaminase minimises ethylene production in the plant. Further, the synthesis of plant auxins like indole-3-acetic acid (IAA), solubilization of phosphate in soil, and siderophore production can also influence plants' HMs uptake. Bioaugmentation of such bacterial strains with OPs will improve their potential against the HMs tolerance, uptake and accumulation (Roquigny et al., 2017). Lin et al. (2018) reported that the application of phosphate solubilizing bacteria (PSB) with *Wedelia trilobata* (Common name: Singapore daisy), improved plant growth, enhanced Cu adsorption and transportation within the plant. They further concluded that the PSB was tolerant of Cu contamination in soil, even at elevated levels. Heavy metal tolerant bacterial strains can also promote the performance of ornamental plants. Zn tolerant bacterial strains *Bacillus subtilis*, *Bacillus cereus*, *Flavobacterium sp.*, and *Pseudomonas aeruginosa* promoted the *Orychophragmus violaceus*'s (Common name: Chinese violet) the physiological status and metal uptake by (He et al., 2010). The strain *Flavobacterium sp.* with *O. violaceus* showed highest Zn accumulation in shoot and root than the non-inoculated plants.

Similarly, the inoculation of bacterial consortia, consisting of *Rhizobium leguminosarum*, *Bacillus simplex*, *Luteibacter sp.*, and *Variovorax sp.*, improved shoot (59%) and root (56%) biomass of *Lathyrus sativus* L. (Common name: grass pea) under Pb stress in the hydroponic

1 system. Higher Pb translocation in shoot and root (39 and 47%, respectively) was observed,  
2 compared to the non-inoculated plant. All strains were capable of initiating root nodulation,  
3 synthesis of IAA, siderophore production, phosphate stabilization. Hence, an inference can be  
4 made that the use of bacterial strains can improve the growth of OPs, and due to the scarcity of  
5 data in this domain, more research is needed.  
6  
7  
8  
9

#### 10 **4.3.2. Fungi**

11 *Aspergillus*, *Mucor*, *Penicillium*, and *Trichoderma* genera of filamentous fungi are well known  
12 for their ability to tolerate heavy metal stress (Tiwari and Lata, 2018). The use of arbuscular  
13 mycorrhizae (ABM) and ectomycorrhizae (ECM) fungi can influence plant growth. Further, it  
14 can also affect the HMs mobility within in rhizosphere and different plant compartments  
15 (Lajayer et al., 2019; Liu et al., 2017). Like bacteria, Fungi are found ubiquitously in the  
16 environment and are reported to improve biomass and yield of associated plants, by mitigating  
17 the biotic and abiotic stress, improving the plant nutrient availability, providing barrier and  
18 tolerance to the contaminants. They also compete and inhibit potential pathogenic micro-  
19 organism within plant and rhizosphere (Khan et al., 2017ab). The symbiotic relationship  
20 between ABM and plants reduces HM toxicity and uptake by sequestering the HM in fungi  
21 (Lajayer et al., 2019). Khan et al. (2017) reported that *Glomerella truncate* and *Phomopsis*  
22 *fukushii* inoculation with *Solanum nigrum* L. increased the Cd tolerance of the plant at high  
23 concentrations (25 mg Cd kg<sup>-1</sup> sand DW). The methods of HMs complexation were also  
24 reported for the fungal strains that can promote plant growth. It is achieved using organic  
25 compounds and immobilization through chemical bonding to the cell wall (Khan et al., 2017;  
26 Luo et al., 2014). One such study was conducted by Tabrizi et al. (2015), in which *Calendula*  
27 *officinalis* L. was cultivated with ABM fungi (*Glomus mossea* and *G. intraradices*). The results  
28 indicated higher Pb and Cd accumulation in root and shoot than the plant with no association.  
29 Fungal associations with plants are also reported to trigger the gene expression pattern of plants.  
30 Still, there is a lack of research in this domain, and further investigation is needed to defend  
31 this claim.

#### 51 **4.4. Introduction of the transgene in OPs**

52 One of the most crucial aspects of maintaining a good phytoremediation strategy is the  
53 genotype of the plant. Most of HM accumulation characteristics, tolerance, translocation, and  
54 compartmentalization are dependent on it (Lajayer et al., 2019). The HMs metabolism is a  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 complex mechanism reliant on the biotic and abiotic surroundings. Transformation of plants  
2 using transgenes is one of the popular options to overcome HM stress and toxicity (Koźmińska  
3 et al., 2018). Table 4 discussed the transgenic OPs reported for HMs remediation or tolerance.  
4 Strategies commonly adopted include transformation with genes responsible for uptake,  
5 translocation, stabilization, compartmentalization, and sequestration of HMs. Such  
6 modification leads to making plants capable of producing higher biomass, fast-growing,  
7 increased tolerance and resistance to multiple HMs (Koźmińska et al., 2018; Lajayer et al.,  
8 2019).

14 In OPs introduction of tolerance, genes can confer higher tolerance. The study conducted by  
15 Wu et al. (2011) summarized that *Petunia hybrida*, transformed with an *Arabidopsis CAX1*  
16 variant (*CAXcd*) was capable of tolerating and accumulating higher levels of Cd (2.5 times  
17 higher), than the control plants. Another approach to improve the tolerance of OPs is the  
18 introduction of bacterial/fungal catabolic or plant growth-promoting genes. The transformation  
19 of *Petunia hybrida* with bacterial genes 1-aminocyclopropane deaminase (ACC) and  
20 tryptophan/indole-3-acetic acid monooxygenase resulted in better biomass and height of  
21 transgenic compared to the wild control plants (Zhang et al., 2008). The addition of these genes  
22 can lead to fruitful results with other plants, as the biomass is a limiting factor in most  
23 phytoremediation studies. Another scheme that can be used for the transformation of OPs is  
24 introducing genes coding for metal chelators called phytochelatins (Koźmińska et al., 2018).

36 Depending on the source of gene and model used, one of the issues that can arise upon the  
37 transformation of OPs with PCs from other plants is that PCs' expression and production can  
38 affect the HMs transpiration and compartmentalization significantly in the transgenics. The  
39 transformation of *Populus tomentosa* Carr. (Common name: Poplar plant) phytochelatin  
40 synthase (*PtPCS*) gene into *Nicotiana tabacum* L. resulted in lower Cd translocation into the  
41 aerial parts of *PtPCS* transgenics (Chen et al., 2015). Contrary to this, Shukla et al. (2013)  
42 reported that the transformation of *Ceratophyllum demersum* L. (Common name: Coontail)  
43 phytochelatin synthase (*CdPCS<sub>I</sub>*) in *Arabidopsis* plant improved Cd and As accumulation and  
44 uptake. Co-overexpression of multiple genes responsible for metal homeostasis in OPs can also  
45 be interesting, and by this approach, a potential hyperaccumulator can be obtained (Koźmińska  
46 et al., 2018).

57 It was proven by the findings of Zhao et al. (2014). According to them, co-expression of a  
58 *Phragmites australis* (Common name: Reed) glutamyl cysteine synthetase gene (*PaGCS*) with  
59

*P. australis* PC synthase (*PaPCS*) in *Festuca arundinacea* (Common name: Tall Fescue) improved the PCs activity, and due to co-expression of both genes, the double transgenic plant of *F. arundinacea* performed higher Cd translocation and accumulation, in comparison to the wild-type and single gene transformed plants (Zhao et al., 2014).

## 5. Case studies related to OPs & OTs mediated HMs remediation

The field application of OPs for removing HMs is practised in a different part of the world. The results and response of these applications remained encouraging. For instance, flowering OPs belonging to *Canna*, *Iris*, *Heliconia*, and *Zantedeschia* were reported to improve the efficiency of constructed wetland up to 30% compared with constructed wetland without flowering OPs (Sandoval et al., 2019). While in some places OPs show limited or no positive impact of phytoremediation. To overcome this issue, the synergistic application, along with the method explained in Table 3. One such study was conducted in Alborz city, Iran. It was found that the simultaneous addition biosolids, collected from the Tehran based urban wastewater treatment plants, along with cow manure significantly improves the growth and HMs (Ni, Pb, and Zn) accumulation capacity of *Helianthus annuus* L. (Yazdanbakhsh et al., 2020). These resulted were also supported by the previously conducted study by Mukhtar et al., (2010).

Chengli et al., (2020) reported a case study for the impacts of OPs on the soil heavy metal pollution (Cd, Cr, Cu, Pb and Zn) in Kaifeng City, China. The studied OPs included *Argyranthemum frutescens*, *Chrysanthemum morifolium*, *Dendranthema morifolium*, and *Tagetes patula*. It was proposed that the use of OPs benefited Kaifeng city's environment as these OPs helped in daily dust retention, released oxygen released and fixed carbon dioxide content per day, which is increased by increasing the OPs cultivation density. The OPs showed the following absorption capacity: Cr > Cd > Pb > Zn > Cu, with *C. morifolium* showing the best response.

Aquatic and terrestrial OPs can be used to remove nutrient and heavy metals (Cr, Pb, Cd) in the wastewater. *Iris pseudacorus* L. and *Acorus gramineus* Soland (Common name: Japanese sweet flag) were considered terrific selections for managing composite-polluted urban wastewater (Zhang et al., 2007). The availability of freshwater is expected to get scarce in the urban centre, and hence using greywater ornamental plants will be cultivated. This greywater can contain the nutrient and thus promote plant growth. Shaharoon et al., (2019) conducted one such study in Oman. It was found that 28% of respondents use wastewater for irrigation,

as it is believed that it can help improve plants growth and yield due to the nutrient richness. This trend will surely be rise further, as more people are shifting to urban and suburban areas, with time.

*Polianthes tuberosa* (Common name: Teberose) was used by Singh and Srivastava, (2016) for the removal of HMs (Cu, Zn, Ni, Al, Pb, and Fe) from domestic wastewater in horizontal subsurface flow constructed wetland. It was discovered that HMs concentrations followed the following biological concentration factor trend  $Al \gg Zn > Cu > Ni > Pb > Fe$ . Further, the compartmentalization was highest in roots, followed by rhizomes, leaves, and inflorescence, respectively. It is a way wastewater can be treated, and the flower cuttings and potted OPs can be sold to generate revenue. Similarly, HMs contaminated CWs can also be subjected to treatment using OPs. Aquatic OPs *Pontederia cordata* (Common name: Pickerelweed) has been reported as a prospective OPs the phytoremediation of Cd contaminated wetlands, sequestering 50–77% of the  $Cd^{2+}$  in the plant roots (Xin et al., 2020).

The OPs and OTs can be used to study the fluctuations in HMs of a region. Sevik et al., (2020) reported a study in which HMs (Pb, Co, and Fe) concentrations tree rings (the inner and outer bark) of Cedar tree (*Cedrus sp.*) cut by the end of 2016, in Kastamonu province, Turkey. It was done to perform a retrospective investigation of atmospheric HMs in 2016. It was found that the HMs were in higher concentration in the road-facing bark than in the inward-facing bark. Hence, OTs' collected biomass can also be used to study the impact of HMs and particulate matter on human health (Manzoor et al., 2016). Turkyilmaz et al., (2019) also proposed the same outcomes in a case study conduct in Ankara, Turkey, by analysing HMs deposition in *Quercus laevis* rings.

## 6. Challenges and future perspective of OPs mediated HMs phytoremediation

In the recent decade, the picture of soil as an inert solid matrix that passively presents its services to the ecosystem's abiotic and biotic components has been changed. It is recognized as the dynamic matrix, having complex biological, chemical, and physical interactions, which play an essential role in shaping the microbial diversity, the fate of a nutrient and contaminant by regulating the biogeochemical cycles and affecting human, animals, and plants (Khan et al., 2019c). Hence soil plays a significant role in the overall ecological processes in science and engineering, well recognized in the academic and professional world (Cecchin et al., 2017). Similarly, water is also recognized as a dynamic body (Rinke et al., 2019). The removal of HMs

with biological methods, notably, phytoremediation has received much attention in recent decades. Heavy metals are non-degradable, and if no attention is given to this, the xenobiotic concentration of HMs will end up into one of the environmental compartments (Tiwari and Lata, 2018). Many methods can be adapted to implement successful phytoremediation of HMs contaminated site using OPs, which were discussed previously in section 4 of this review. Still, certain obstacles should be kept into consideration while designing the OPs mediated phytoremediation. Several strategies have been successfully applied to generate plants which can grow in metal contaminated soils and accumulate or tolerate metal stress.

The notable challenges and their prospects for successful remediation or recreational strategy using OPs for the HMs contaminated site are summarized in Figure 2. The most crucial factor in phytoremediation is the potential plant's choice (Thakur and Sharma, 2016). The response of plants to HMs is highly variable, as different factors play a significant role in it, which included ecotype of plant, and specific HM tolerance. Furthermore, the tolerance against one metal is not sure whether the same plant can tolerate other HMs. That's why many selected HMs accumulators, and hyperaccumulators failed at the field and industrial scale (Sharma et al., 2016; Thakur and Sharma, 2016). Rigorous screening for tolerance against HMs and site-specific parameters is needed for successful implementation of phytoremediation. The site-specific parameters that should be considered include temperature, water availability, soil conditions, HMs contamination levels, presence of other contaminants, and economic factors.

Further, the impact of plant-microbe associations concerning ornamental plants has not been investigated in-depth, in previous studies. Another challenge is to overcome the problem of heterogeneous contamination of the contaminated sites. The fruitfulness of HMs remediation with OPs should be tested against multi HMs. With this strategy, a minimal depiction of the original site can be achieved, while these findings' output will become more practical. The same idea was also proposed by Thakur and Sharma (2016). They suggested that for successful phytoremediation in field conditions, each site's complexity should be considered, as the choice of plant and associated axillary things varies with site conditions.

The selection of the phytoremediation process is also critical. It is essential as the end-product can carry a higher level of HMs if the used plant was an HM hyperaccumulator. The HMs are non-degradable so; a secondary HMs stabilization process is needed. The inappropriate disposal of the harvested plants can raise environmental concerns due to the high load of HMs (Aftab et al., 2020). The secondary process that can be adopted includes pyrolysis, where the

1 plant residues can be converted into catalytic carbon, as reported by Álvarez-Mateos et al.  
2 (2019). They converted *Jatropha curcas* L. (Common name: Jatropha) biomass, generated after  
3 the process of phytoremediation of the highly contaminated mining site, into catalytic carbon  
4 by the process of pyrolysis. Production of biochar from residues of OPs caused after HMs  
5 phytoremediation is also reported. *Silphium perfoliatum* L. (Common name: Cup plant)  
6 containing high levels of Cd, Pb, and Zn was successfully converted into biochar, that stabilized  
7 the already absorbed HMs, and HMs were further stabilized through adsorption to produced  
8 biochar (Du et al., 2019).  
9  
10  
11  
12  
13  
14

15 Metal(liod) recovery and valorisation can also be used for the stabilization of HMs. Eze and  
16 Harvey (2018) reported the phytoremediation of As containing soil (200 mg kg<sup>-1</sup>) with the help  
17 of *Pteris cretica* (Common name: Cretan brake fern). The biomass is used to produce valuable  
18 As products (including As nanoparticles (NPs), and magnesium arsenate). Another attractive  
19 alternative that can be used is phytomining. In phytomining, the HMs containing plant parts  
20 can be converted into bio-ores, which is achieved by the controlled combustion of plant residues  
21 of the harvested plants resulting in ash's energy production and formation (Ali et al., 2013). The  
22 resulting ash can be used for metal recovery and recovered metals and metalloids can produce  
23 green NPs. A study conducted by Keshavarzi et al. (2018) reported Au ion bio-reduction to Au  
24 NPs, using three different varieties, Nikshahri, Hamedani, and Yazdi, of Iranian *Medicago*  
25 *sativa* (Common name: Alfalfa). They found that at pH 4.7 with a three mM Au ion  
26 concentration Hamedani variety was best for green production of Au NPs. In another study,  
27 Gul et al., (2020) evaluated the extraction and recovery of Pb using *Pelargonium hortoum*  
28 (Common name: Garden geranium). Flowers of OPs also have economic value as they can be  
29 sold (Khan et al., 2020a; Mushtaq et al., 2020). They can also be used to produce essential oils  
30 for fragrances (Lajayer et al., 2019). To date, no report supports the presence of HMs in OPs  
31 essential oil and further research in this domain is also needed. Participation of professional  
32 belonging to environmental, and landscape science and stakeholders, including enterprises and  
33 responsible authorities is essential. This mutual collaboration will result in positive outcomes  
34 in the provision of sustainable results from clean-up missions and practical employment of  
35 more environmentally friendly technologies with close to zero emissions that are important in  
36 the scope of minimizing climate change problems.

19  
20  
21  
22  
One primary consideration needed for the final and effective utilization biomass produced after the HMs remediation. It requires the development of biomass management acts and policies after phytoremediation. As suggested by Song and Park (2017), the first stage is to prohibit the use of toxic residues in compost. For this, there are many instruments and legal codes around the world. Among the notable examples of acts that mention control mobility of hazardous waste, includes “Hazardous Substances Rules, 2003” in Pakistan, “Hazardous and Other Wastes (Management and Trans-boundary Movement) Rules, 2016” in India, “Wastes Control Act (Act Number 13038)” in South Korea, “Urban Waste Water Treatment Directive (91/271/EEC)” and “Sewage Sludge Directive (86/278/EEC)” in Europe, and “Solid Waste Disposal Act (Public law 89-272)” in USA. However, none of these acts or laws specifically concerned with post-remediation biomass. It is therefore vital to improve the management of contaminated biomass additional legislation should be considered.

23  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
Further, the promotion of post-remediation biomass usage proven safe for consumption, as per the first-stage policy measures, is the second measure needed to be implemented for effective policymaking and execution. Therefore, any government must set out obligation through national environmental quality standards (NEQS). These NEQS can prevent phytoremediation biomass related secondary pollution, cut the cycle of toxic pollutants, and promote close-loop cycling of biomass using environmentally acceptable and sustainable methods.

63  
64  
65  
As the OPs mediated HMs phytoremediation is dual advantageous, for both recreational and remedial purposes, interdisciplinary nature research must be done, to identify the depth of knowledge and to improve the overall process. Extensive screening of OPs is needed to find HMs tolerant, accumulator, and hyperaccumulators. The use of biological (natural and synthetic) and chemical amendment must be exposed with OPs for HMs phytoremediation. The OPs currently used (commonly and extensively), plants belonging to *Asteraceae*, *Liliaceae*, *Nicotiana*, *Nymphaeaceae*, *Petunia*, and *Rosaceae*, must be exposed first their agronomic practice are well developed. The results contribute to the knowledge of phytoremediation and reduce the risk of economic loss to the horticulture market of the studied plants.

A well in-depth risk assessment is needed to be conducted to quantify the benefits or shortcomings of OPs over other crop and previously used plants. A cost-benefit analysis will be beneficial to quantify the efficacy of OPs in phytoremediation and applicability of green

1 technologies. The better understanding of metal, soil, microbes, and plant roots the key four  
2 rhizosphere players will quantify the improvement or negative impacts of HM-OPs interaction.  
3 The current knowledge of plant HMs exposure must be extended from single HM exposure to  
4 multiple HMs conditions, as in real condition the site is contaminated with numerous  
5 contaminants. The OPs have shown promising results when cultivated on synthetic wastewater.  
6 Ornamental Plants like *Celosia argentea* L., *Catharanthus roseus* (L.) G. Don, *Petunia hybrida*  
7 L., *Nicotiana glauca* L. are among the example of few recently tested plant against such  
8 heterogenous HMs contaminated wastewater (Iqbal et al., 2019; Khan et al., 2019b; Mushtaq  
9 et al., 2020).

10  
11  
12  
13  
14  
15  
16  
17 In vitro testing system should be established to preserve the time required to test potential OPs,  
18 which can tolerate/remediate the contaminate(s). These include tissue culture, plant enzymes  
19 and extracts, components of live plants, and soilless media like hydroponics. Such systems  
20 allow quick characterization of plants for their effectiveness in tolerating, accumulating, or  
21 degradation of contaminant(s). A few examples are presented in Table 5. Further, OPs must be  
22 tested for other pollutants like hydrocarbons, pesticides, dyes, antibiotics, and persistent  
23 organics. The OPs *Acorus calamus* performed remediation of soil co-contaminated with  
24 cadmium and polycyclic aromatic hydrocarbons (Jeelani et al., 2017). Similarly, Chandanshive  
25 et al., (2018) reported efficient removal of dyes from textile wastewater, stabilising HMs (Cd,  
26 As, Pb and Cr) using *Tagetes patula*, *Aster amellus*, *Portulaca grandiflora* and *Gaillardia*  
27 *grandiflora*. The potential of OPs extends to the removal of antibiotics. Li et al., (2020) reported  
28 that *Mirabilis jalapa* L. and *Tagetes patula* L. are favourable OPs intended to remediate  
29 alkaline soil co-contaminated with Cd and tetracycline.

30

34  
35  
36  
37  
38  
39  
40  
41  
42 The International Union of Pure and Applied Chemistry and other forums must address to  
43 update the definition of HMs and prepare the periodic table according to HMs toxicity.  
44 Unfortunately, trace metals do not fit for Cd, Ni, and Pb in the current scenario, as they are not  
45 needed even in the minute concentration by plant and animal. At the same time, terms can be  
46 used with some reservation for Cu and Cr. Duffus (2002) also proposed a periodic table  
47 classification based on the understanding of the chemical basis of toxicity and toxic effects to  
48 be predicted.

## 49 50 51 52 53 54 55 56 **9. Conclusions**

1 The use of OPs brings dual benefits, remedial and recreational at the same time, so their  
2 use must be promoted when designing the HMs phytoremediation strategy. They offer a  
3 reduced risk of biomagnification as compared to the crop plants. This work focused on the  
4 mechanisms of HMs toxicity to plants, the possibility of using OPs in HMs phytoremediation,  
5 and methods to improve their growth in field conditions. The most critical factor for HMs  
6 phytoremediation is selecting native OPs; this will reduce the time required for initial screening.  
7 It is important to note that HM-OPs interaction can reduce OPs growth and biomass, which can  
8 be improved with the use of soil conditioners, appropriate OPs-microbe interactions, and the  
9 introduction of transgenes, or/and use of synthetic and organic compounds. These substitutions  
10 will improve plant growth by HMs compartmentalization, sequestering, and detoxification. It  
11 is achieved through a range of enzymatic and non-enzymatic antioxidants, reducing the toxicity  
12 to aerial parts and plants' roots. Further, the detailed mechanisms of HMs toxicity, sequestering  
13 and compartmentalization using OPs with other amendments are needed to be investigated. The  
14 risk assessment associated with the valuable products formed by OPs grown on HMs  
15 contaminated site; specifically pot plants, cut flowers, and essential oils, is another crucial thing  
16 that is needed to perform.
