Lecture 2

Multiprocessor architectures:
distributed memory MIMD
(multicomputers)

José M. Cámara (checam@ubu.es)

v. 1.0

Introduction

- Loosely coupled hardware computers.
- There are different coupling levels within this category according to the hardware elements shared: storage, input/output...
- Since no shared memory is available, communication is obtained via message passing mechanisms.
 - Message: information exchange unit.
 - Packet: commutation unit.

Switching

- Circuit switching: a permanent channel is established for the transmission of the whole message.
- Packet switching techniques (flow control):
 - Store and forward: $T = (L/W)(N-1)$
 - Wormhole: $T = (L/W) + (F/W)(N-2)$
 - Virtual cut through: $T = L/W + (P/W)(N-2)$

Packets: headed by destination and position within the message information.

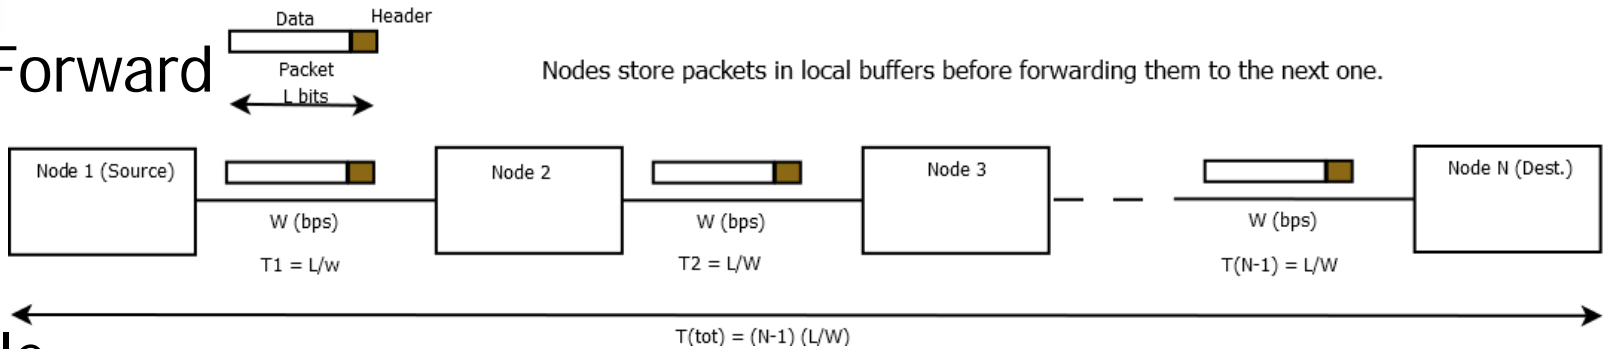

Flit (flow control unit): have no such information except the head flit.

Phit: smallest possible information unit; number of data wires in the link.

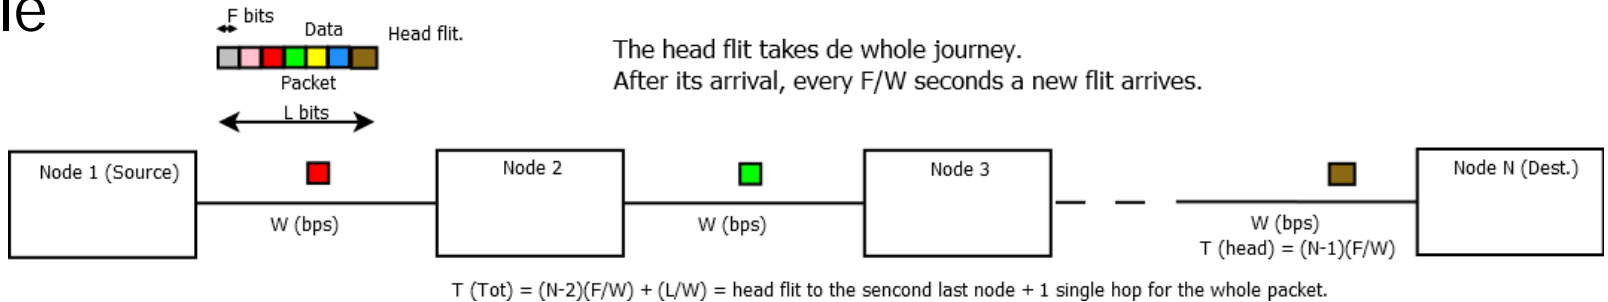

VCT pipeline is analogous to Wormhole but it requires storage space for full packets, just as S&F does.

Flow control techniques

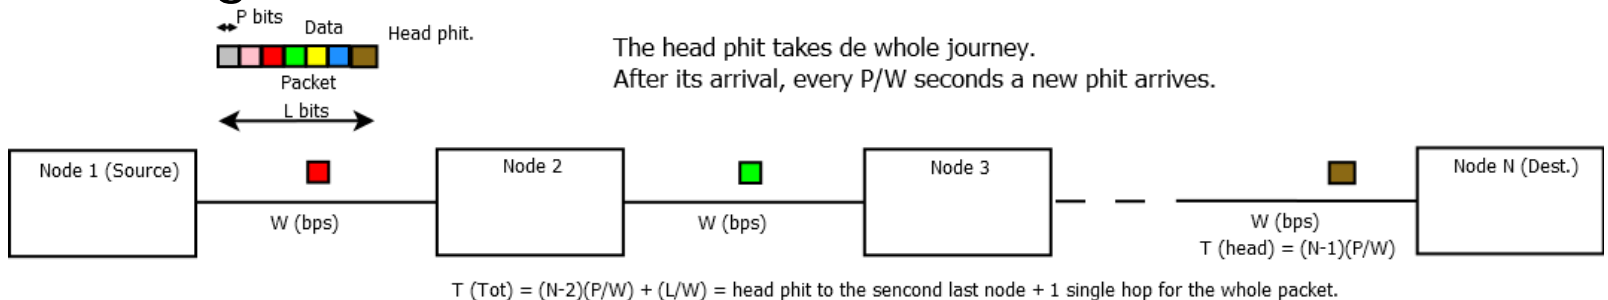

Store & Forward

Wormhole

Virtual cut through

Packet switching

- Issues:

- Flow control: when and how packets move. Involves:
 - Collision management (specially when buffering resources are scarce).
 - Routing: how to make packets find their way to destination.
- Deadlock: packets end up in a closed loop -> network collapses.
- Livelock: packets loops around the network for ever.
- Starvation: a packet is never serviced and gets indefinitely stranded in a buffer.

Deadlock & starvation

Traffic deadlock

http://fedoraproject.org/wiki/FAD_SP_2013

Potential starvation situation
Cars coming from the streets in the lower half
may not be able to enter the roundabout.

Packet switching

Solutions:

■ Deadlock

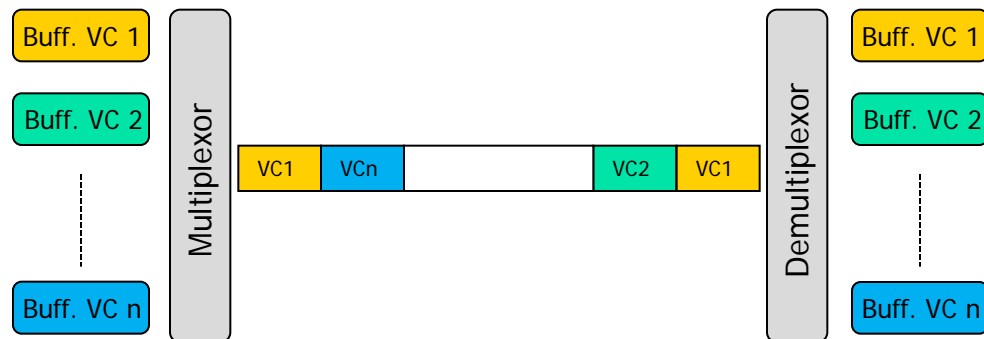

- Virtual channels to defer deadlock formation
- Avoiding: certain algorithm – interconnect combinations are deadlock free.
- Recovery: once the deadlock is produced, the system discards a packet. The sender is inform so it can re-try.

■ Collision management

- Discard
- Store
- Forward -> livelock
- Stall

■ Routing

- Routing algorithms

Time multiplexed virtual channels

[Multimedia content available](#)

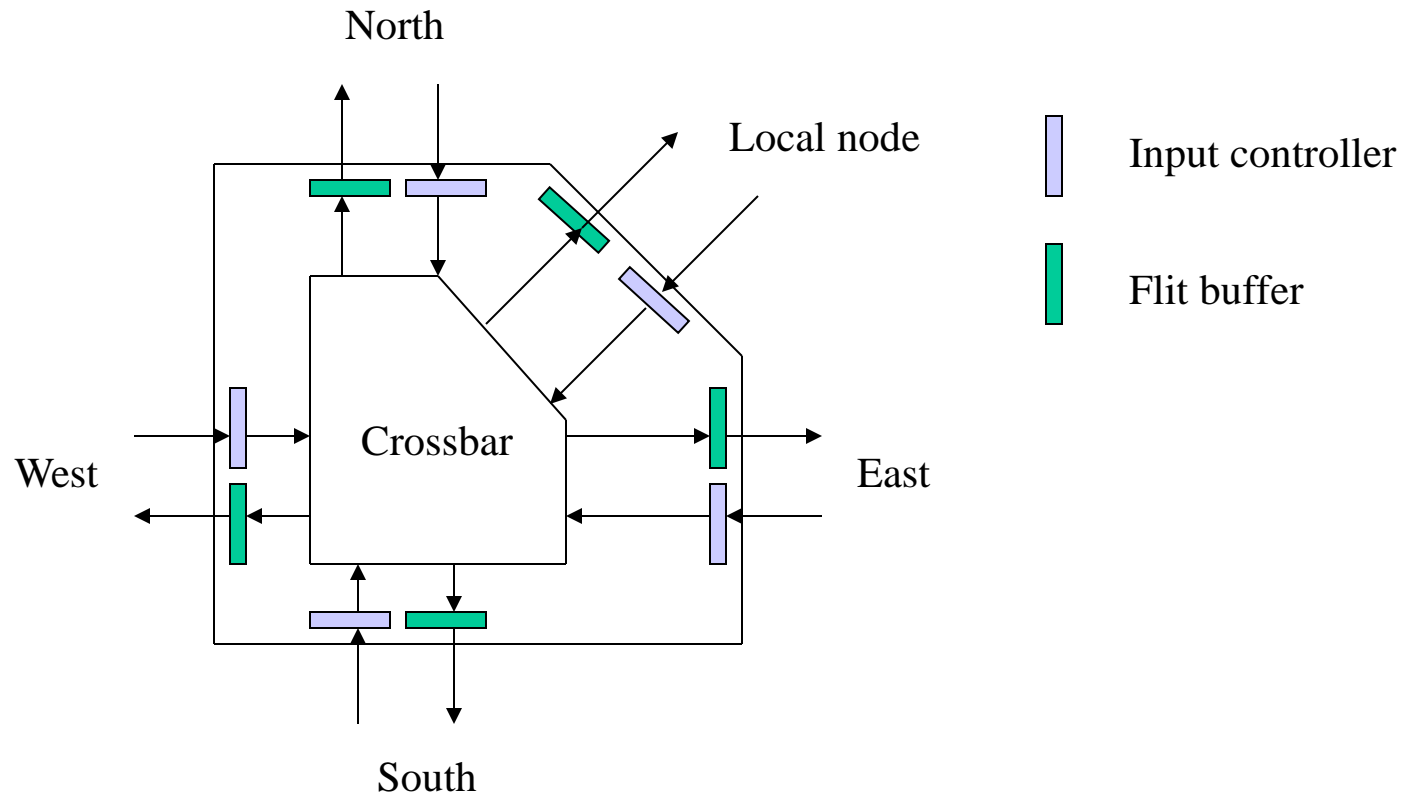

Routing algorithms

- Classification criteria:
 - Number of destinations: unicast, multicast
 - Decision making: centralized, source, distributed
 - Implementation technique: table look-up, finite state machine
 - Adaptivity: deterministic, adaptive
 - Number of alternative ways: partially adaptive, fully adaptive
 - Progressiveness: progressive, backtrack
 - Minimality: minimal (greedy), non minimal (nongreedy)
-> livelock

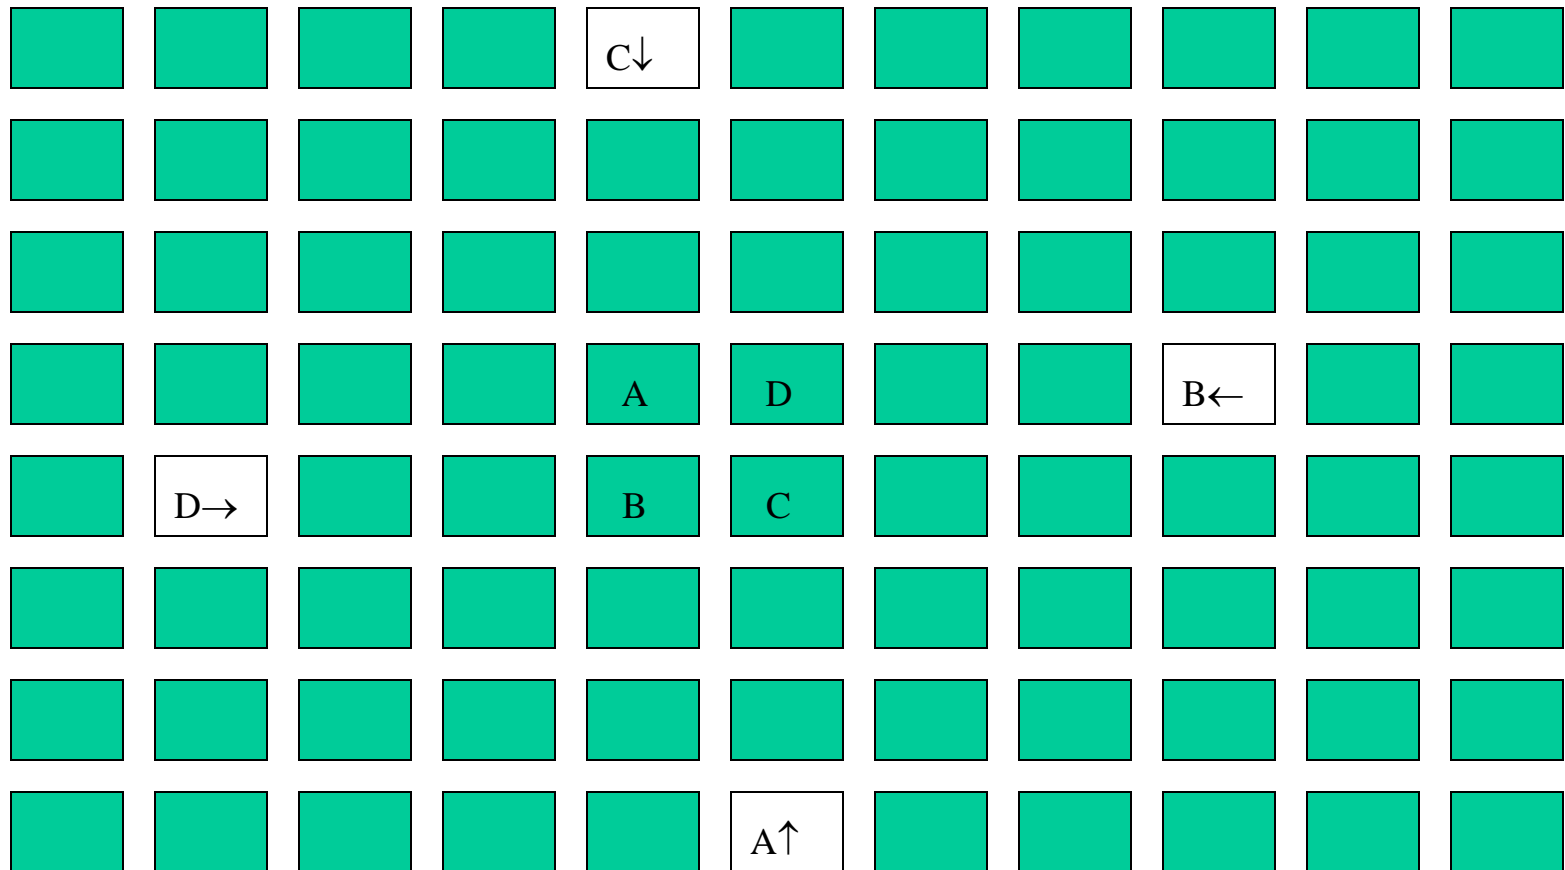

Packet switching

Routing algorithm example

- Topology: mesh.
- Type of algorithm: unicast, progressive, centralized, minimal.
- According to its implementation it may be:
 - Deterministic o adaptive.
 - Table look-up or finite state machine.
- Compatible with DOR.
- Consists of subtracting the coordinates of the source node from those of the destination one.
- The route for a packet to travel from node (2,8) to node (12, 6), comprises $12 - 2 = 10$ hops in x^+ direction and $6 - 8 = 2$ hops in y^- direction.
