<sup>1</sup> This paper is part of the Doctoral Thesis of F. Aguilar.

Experimental excess enthalpies of the ternary system dibutyl ether (DBE) + cyclohexane + 1-butanol and the corresponding binary systems at 298.15 K are reported. A quasi-isothermal flow calorimeter has been built and tested to make the measurements. All the binary and the ternary systems show endothermic character. The experimental data have been fitted using a polynomial equation for the

binary and ternary systems. The values of the standard deviation indicate good agreement between the experimental results and these calculated from the equation.

## Introduction

The use of oxygenated compounds as gasoline-blending agents has been proposed to reduce emissions of new reformulated gasoline. Ether + alkane + alcohol mixtures are of interest as model mixtures for gasoline in which the alcohol and the ether act as non-polluting, high octane number blending agents. From this point of view the study of the ternary mixture dibutyl ether + cyclohexane + 1-butanol is very interesting. Cyclohexane is an usual compound of gasoline; dibutyl ether (DBE) is used as blending agent in reformulated gasoline and 1-butanol is a basic component in the synthesis of the ether, and therefore is always contained as an impurity. Experimental excess enthalpies of the ternary system DBE + cyclohexane + 1-butanol and the corresponding binary systems at 298.15 K are reported in this work. Excess enthalpies have been measured with a new quasi-isothermal flow calorimeter recently built at the University of Burgos. The experimental data have been fitted using a Redlich-Kister<sup>1</sup> equation and NRTL<sup>2</sup> and UNIQUAC<sup>3</sup> models. The values of the standard deviation indicate the agreement between the experimental results and these calculated from the equations.

#### **Experimental Section**

*Materials.* All the chemicals used here were purchased from Fluka Chemie AG and were of the highest purity available, chromatography quality reagents (of the series puriss p.a.) with a stated purity >99.5 %. All reagents were checked by gas chromatography, and the values of purity obtained were >99.6 % for DBE, >99.9 % for cyclohexane and >99.8 % for 1-butanol. The water content for 1-butanol was checked to be less than 0.009%.

*Apparatus and Procedure.* Excess enthalpies have been measured with a new quasi-isothermal flow calorimeter recently built at the University of Burgos, based on the previous experience of the research group.<sup>4,5</sup> Figure 1 shows schematically the quasi-isothermal calorimeter. Two precision positive displacement pumps (Agilent, model 1100) deliver the liquids through stainless-steel tubing at

#### Page 3 of 25

#### Submitted to Journal of Chemical & Engineering Data

programmable constant flow rates into the mixing coil sitting in the flow cell, which is included in the measure unit, following the scheme shown in Figure 2. The flow cell has been built in the TERMOCAL laboratory at the University of Valladolid. In case of binary systems, the two liquids are the pure components and, in case of ternary systems, one of them is a pure component and the other the corresponding binary mixture. The flow cell is immersed in a water bath, (Hart Scientific, model 6020E) thermostatted at the temperature the mixing process is taking place. The stability of the temperature is better than  $\pm 0.01$  K. The bath temperature is measured by its calibrated standard PRT-100, resolving 10 mK in the reading of temperature and estimating an overall uncertainty of  $\pm 30$  mK.

Isothermal calorimetry is based on measuring the energy required to maintain the mixing vessel at a constant temperature. To achieve this condition, a Peltier cooler removes at a constant rate energy from the flow cell and a control-heater compensates this energy and additionally the energy liberated (exothermic) or absorbed (endothermic) by the mixing process and maintains the temperature of the flow cell constant. The variation of temperature is detected by a control sensor, a NTC thermistor. The resistance is measured by a 4-wire resistance bridge with a micro-ohm meter from Hewlett-Packard, model HP-34420A. The Peltier cooler, the control-heater and the calibration heater are connected, each one, to its respectively DC power supply. The control of these devices is made by a computer through a GPIB connection and a specific software that has been developed. The change of heating power of the control-heater before, during and after measurements is a direct measure for the excess enthalpy  $H^{E}$ . The calibration of the measurement system is made by simulating an exothermic mixing process by a calibration resistor.

Knowing the volumetric flow rates delivered, the molar masses and the densities of the pure compounds, the mole fractions of the mixtures obtained in the mixing coil can be calculated. The maximum absolute uncertainty of mole fraction at equimolar composition is  $\pm 0.0008$ . Densities of pure liquids are determined interpolating density data obtained from Riddick et al.<sup>6</sup> at the measured temperature of delivery. Table 1 shows agreement between our estimated density data and literature data. The temperature of pure liquids is measured by a calibrated standard PRT-100 inserted in the pump

body, using as indicator an a/c resistance bridge (ASL model F250) resolving 1 mK in the reading of temperature and estimating an overall uncertainty of  $\pm$  10 mK. Mixtures of different compositions are studied by changing the ratio of flow rates and in this way the dependence of  $H^E$  on mole fraction can be determined. The estimated relative uncertainty of the determined  $H^E/J \cdot mol^{-1}$  is  $\pm 0.01 \cdot H^E$ .

To check the above apparatus we have used two systems traditionally considered as test systems for calorimetric techniques: cyclohexane + hexane and benzene + cyclohexane at 298.15 K. The first system, cyclohexane (1) + hexane (2), was measured by Marsh and Stokes<sup>12</sup> with an isothermal displacement microcalorimeter. This work presents the most complete amount of data and is taken as reference system. However, we have considered also the comparison with data from Murakami et al.<sup>13</sup>, which used a continuous dilution calorimeter, and from Gmehling et al.<sup>14</sup>, whose data were taken with an isothermal flow calorimeter of the same characteristics as ours. Table 2 presents the results found in the references for this system and the results obtained in this work, as well as the maximum deviation of the excess enthalpy respect the calculated value, max $|\Delta H^E|$ , and the standard deviation, rms  $\Delta H^E$ . The Redlich-Kister equation is used for the adjustment of each data set, with the number of parameters employed by each author:

$$H^{E} = x \cdot (1-x) \cdot \sum_{i=1}^{n} A_{i} \cdot (2x-1)^{i-1}$$
(1)

The comparison of the calculated values of the Redlich-Kister coefficients and scattering parameters in this work with those from the literature, shows that our values are similar with regard to the same type of isothermal flow calorimeter and more scattered in relation with isothermal displacement microcalorimeter and continuous dilution calorimeter.

A comparison between experimental data of this work and those from the literature is presented in Figure 3. For each data set, the calculated enthalpy  $H^{E}_{calc}$  has been determined using the Redlich-Kister coefficients of the correlation determined by Marsh and Stokes<sup>12</sup>. The scattering of experimental data obtained in this work is within the ±1% of the calculated enthalpy corresponding to each mole fraction in the central range of composition.

#### Page 5 of 25

#### Submitted to Journal of Chemical & Engineering Data

The second test system is the binary mixture benzene (1) + cyclohexane (2) at 298.15 K. In a similar way as for the former system, comparison between the data of Ewing et al.<sup>15</sup>, Lundberg<sup>16</sup>, Savini et al.<sup>17</sup> and this work is reported in Table 2 and Figure 3, being the coefficients of Ewing et al.<sup>15</sup> used to obtain the calculated enthalpy  $H^{E}_{calc}$  for each data set. In this case, also the agreement between this work and literature data is within the ±1% of the calculated enthalpy.

# **Results and Discussion**

The experimental excess molar enthalpies obtained in this work for the binary mixtures DBE (1) + cyclohexane (2), DBE (1) + 1-butanol (3) and cyclohexane (2) + 1-butanol (3) at 298.15 K are listed in Table 3.

For binary systems, there are several models and empirical equations proposed to fit the  $H^E$  measurements. One of them, the Redlich-Kister equation, is given by eq. 1, in which the  $A_i$  coefficients are determined by the unweighted least-squares method. Another equation very employed is the modified Margules eq. 2, proposed by Abbot and van Ness<sup>18</sup>

$$H^{E} = x_{1}x_{2}RT \left[ a_{21}x_{1} + a_{12}x_{2} - \frac{x_{1}x_{2}b_{12}b_{21}}{b_{21}x_{1} + b_{12}x_{2} + x_{1}x_{2}(c_{21}x_{1} + c_{12}x_{2})} \right]$$
(2)

Binary systems have also been correlated using NRTL model, which expression for the molar excess enthalpy is indicated by the eq. 3:

$$H^{E} = -RT \sum_{i=1}^{n} x_{i} \eta_{i}$$
(3)

where  $x_i$  is the mole fraction of the component *i* and  $\eta_i$  is given by

$$\eta_{i} = \frac{\sum_{k=1}^{p} x_{k} \tau_{ki} G_{ki} \left[ \alpha \left( \tau_{ki} - \left( \sum_{n=1}^{p} x_{n} \tau_{ni} G_{ni} / \sum_{l=1}^{n} x_{l} G_{li} \right) \right) - 1 \right]}{\sum_{l=1}^{p} x_{l} G_{li}}$$

$$G_{ji} = \exp(-\alpha \tau_{ij})$$

#### Submitted to Journal of Chemical & Engineering Data

The NRTL theory assumes that the excess molar enthalpy of a multicomponent mixture depends only on the binary parameters. In this work, the non-randomness parameter  $\alpha$  was assigned 0.3 for the NRTL model of two parameters, and as an adjustable parameter for the NRTL model of three parameters.

For the UNIQUAC model, the molar excess enthalpy is given by

$$H^{E} = \sum_{i=1}^{n} q_{i} x_{i} \frac{\sum_{j=1}^{n} \vartheta_{j} \Delta u_{ji} \tau_{ji}}{\sum_{j=1}^{n} \vartheta_{j} \tau_{ij}}$$
(4)

where  $\mathcal{G}_i = \frac{q_i x_i}{\sum_j q_j x_j}$  and  $q_i$  the molecular surface area, obtained as the sum of the contributions of the

functional groups presents in the compound.

Results of data correlation for the binary systems are summarized in Table 4. A plot of the experimental and correlated data is shown in Figure 4.

The ternary mixtures DBE (1) + cyclohexane (2) + 1-butanol (3) at 298.15 K were formed by adding the cyclohexane (2) to binary mixtures of fixed composition of DBE (1) + 1-butanol (3). Four different starting binaries were used, with values of the ratio  $x_1/x_3$  of 0.2498, 0.6669, 1.4988 and 4.0531 respectively. The experimental excess molar enthalpies listed in Table 5 are determined by eq. 5, using the smooth representation of  $H^{E}_{13}$  by Redlich-Kister:

$$H_{123}^{E} = H_{2+13}^{E} + (1 - x_2)H_{13}^{E}$$
(5)

Experimental results for the excess molar enthalpy  $H^{E}_{123}$  are shown in Figure 5.

The following equation was used to fit the  $H^E$  measurements

$$H_{123}^{E} = H_{12}^{E} + H_{13}^{E} + H_{23}^{E} + x_{1}x_{2}x_{3}\Delta H_{123}^{E}$$
(6)

with

$$\Delta H_{123}^{E} = B_0 + B_1 x_1 + B_2 x_2 + B_3 x_1^2 + B_4 x_2^2 + B_5 x_1 x_2 + B_6 x_1^3 + B_7 x_2^3$$
(7)

where the parameters  $B_i$  were determined by the unweighted least-squares method. Another alternative for the calculation of  $\Delta H^{E}_{123}$  is eq. 8

#### Submitted to Journal of Chemical & Engineering Data

$$\Delta H_{123}^E = B_1 x_1 + B_2 x_2 + B_3 x_3 \tag{8}$$

Table 6 presents the summary of correlation results obtained for the ternary system with eq. 6, 7, 8, and NRTL and UNIQUAC models. Table 6 also shows the prediction results obtained for the ternary system using the parameters of the binary systems.

The excess molar enthalpy of the system DBE (1) + cyclohexane (2) at 298.15 K shows endothermic behaviour ( $H^E > 0$ ) in the whole range of composition. The best fit of experimental data is obtained with the Redlich-Kister equation with a root mean square deviation, rms  $\Delta H^E$ , of 0.5 J·mol<sup>-1</sup> and a maximum value of the absolute deviation, max $|\Delta H^E|$ , of 1.2 J·mol<sup>-1</sup>. Deviations obtained with NRTL and UNIQUAC models are higher. The maximum value of the molar excess enthalpy is 267 J·mol<sup>-1</sup>, obtained at a mole fraction of DBE about 0.40. Comparison with data for the same binary system and temperature reported by Marongiu et al.<sup>19</sup> shows that our  $H^E$  data are considerably higher, the difference being 15 % in the central range of composition, even when the calorimeter was re-calibrated and the binary system measured three times.

The binary system DBE (1) + 1-butanol (3) measured at 298.15 K is also endothermic. The maximum value of  $H^E$  is 892 J·mol<sup>-1</sup>, at a mole fraction of DBE about 0.60. Modified Margules equation gives the best fit with a root mean square deviation, rms  $\Delta H^E$ , of 2.4 J·mol<sup>-1</sup> at 298.15 K. The maximum values of the absolute deviation, max $|\Delta H^E|$ , is 4.0 J·mol<sup>-1</sup>. The remaining models give worse fits. Our  $H^E$  data agree to within 1,5 % in the central range of composition with the measurements for the same system and temperature obtained from Kammerer and Lichtenthaler.<sup>20</sup>

The third binary system which has been studied is the system cyclohexane (2) + 1-butanol (3) at 298.15 K, showing also an endothermic behaviour. The maximum value of the molar excess enthalpy of the mixture is 635 J·mol<sup>-1</sup>. The mole fraction of cyclohexane at this maximum is approximately 0.65. The experimental data have been fitted by Redlich-Kister, modified Margules, NRTL and UNIQUAC models, being the Modified Margules equation the best fit with a root mean square deviation, rms  $\Delta H^E$ , of 2.6 J·mol<sup>-1</sup>. The maximum value of the absolute deviation, max $|\Delta H^E|$ , is 6.0 J·mol<sup>-1</sup>. Comparison with

data for the same binary system and temperature reported by Löwen and Schulz<sup>21</sup> shows that our  $H^E$  data agree to within 1.7 % in the central range of composition.

Concerning the measured ternary system, the best fit of experimental data is obtained with eq. 6 and 7. The root mean square deviation, rms  $\Delta H^E$ , is of 5.0 J·mol<sup>-1</sup>, and the maximum value of the absolute deviation, max $|\Delta H^{E}|$ , is 13.4 J·mol<sup>-1</sup> which means about 5 % over the experimental molar excess enthalpy at this point. The results obtained with the other models are rather worse. This system shows an endothermic behaviour in the whole range of composition. The maximum value of  $H^E$  is 890 J·mol<sup>-1</sup>. No data of the same system were found in the literature for comparison. Both NRTL and UNIQUAC models present high root mean square deviation values in the prediction of data.

#### Conclusions

Isothermal excess enthalpies at 298.15 K for the ternary system dibutyl ether (DBE) + cyclohexane + 1-butanol and its constituent binary systems were determined by using an isothermal flow calorimeter. ry asyn. All the binary systems show positive values and strongly asymmetric  $H^E$  behavior in the measured temperature. The measured excess enthalpies data were correlated well with various common  $H^{E}$ models.
